

AMERICAN RIVER COLLEGE

# Voltage Drop

**Energy Instructor**

[www.energyinstructor.info](http://www.energyinstructor.info)

# Lesson Plan

- Conductors, PV, and NEC
  - Voltage drop

# Voltage Drop Calculation

- Voltage drop is NOT an NEC code issue
  - It is not a safety issue
  - Still important design consideration (\$\$\$\$)
  - Power =  $I * V$ , as  $V$  drops,  $P$  drops
- Ohms Law
  - $V = I * R$
  - $\Delta V = I * R$  where  $I$  = amperage in conductor,  
R = property of the conductor
- Conductor resistance
  - Decreases as conductor size increases
  - Increases as conductor temperature increases

# Voltage Drop Calculation

- NEC Chapter 9, Table 8 – Conductor properties
  - Direct Current Resistance at 75C
  - Stranded versus solid conductors
  - Copper versus Aluminum
  - Size 18 to 4/0
  - Area, diameter, and Ohm/kFT / Ohm/km

<b>Table 8–1. Conductor Properties, NEC Chapter 9, Table 8</b>			
<b>Conductor Size American Wire Gage</b>	<b>Conductor Resistance Per 1,000 Feet at 75°C</b>	<b>Conductor Diameter Inches</b>	<b>Conductor Area Circular Mils</b>
14 AWG	3.140 ohms (stranded)	0.073	4,110
12 AWG	1.980 ohms (stranded)	0.092	6,530
10 AWG	1.240 ohms (stranded)	0.116	10,380
8 AWG	0.778 ohms (stranded)	0.146	16,510
6 AWG	0.491 ohms (stranded)	0.184	26,240

# Voltage Drop Calculation

- Resistance as a function of diameter
  - How does resistance change if diameter is doubled?

- Resistance as a function of temperature
  - How does resistance change if temp = 150C?

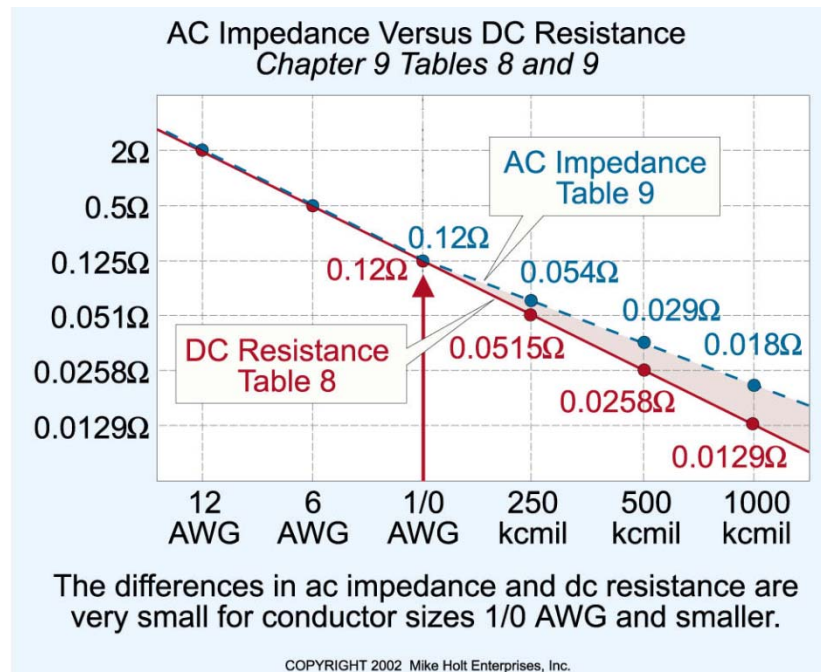

Temperature Adjustment, Table 8, Note 2:

$$R \text{ for CU} = \text{Table R} \times [1 + (0.00323 \times (\text{Temp}^{\circ}\text{C} - 75^{\circ}))]$$

$$R \text{ for AL} = \text{Table R} \times [1 + (0.00333 \times (\text{Temp}^{\circ}\text{C} - 75^{\circ}))]$$

# Voltage Drop Calculation

- What about Alternating Current Resistance?
  - NEC Chapter 9, Table 9
  - More complex considerations
  - Power factor, and effective impedance
  - DC table is fairly accurate for conductors smaller than 2AWG

# Voltage Drop Calculation

- Calculate resistance in conductors

(Uncoated is used, it does not mean uninsulated)

- What is the resistance in 200ft of 12AWG copper stranded at 30C?

$$1.98 \text{ Ohm/kFT} * 200/1000 = 0.396 \text{ Ohm}$$

- What is the resistance of 400ft of 10AWG copper stranded at 100C?

$$1.24 \text{ Ohm/kFT} * 400/1000 * (1 + 0.00323 * (\text{Temp} - 75\text{C})) = 0.536 \text{ Ohm}$$

- What is resistance in circuit between junction box and inverter if distance between them is 300ft and we are using 10AWG copper stranded at 50C?

$$1.24 \text{ Ohm/kFT} * 600/1000 = 0.744 \text{ Ohm}$$

# Voltage Drop Calculation

- What is an acceptable voltage drop?
  - No code requirements
  - Typically measured as a percentage of the nominal voltage
  - 5% or greater bad
  - 2% - 3% is considered “good: design practice
  - What is the voltage drop in 200ft of 12AWG copper stranded at 30C if amperage is 4A?  
$$4A * 0.396 \text{ Ohm} = 1.58V$$
  - If circuit voltage is 12V, what is the percent voltage drop?  
$$1.58V / 12V = 13.2\%$$
  - If circuit voltage is 48V, what is the percentage drop?  
$$1.58V / 48V = 3.3\%$$

# Voltage Drop Calculation

- What amperage do we use in PV voltage drop calcs?
  - The higher the amperage, the greater the calculated drop
  - Rule of thumb:
    - Use Peak Power amperage (IMP) for grid-tied PV currents
    - Use ISC for battery charging circuits PV circuits
    - Use max steady state current of the load
    - Use max steady state current for battery to inverter circuits
- What voltage do we use in PV voltage drop calcs?
  - Doesn't matter if we are trying to measure the actual voltage loss
    - Example calculating voltage drop to make sure on/off set point is not reached
  - Use nominal percentage if you are looking for percentage

Example 4 (breakout into groups and try): (RT=Round Trip)

(Distance must be multiplied by 2 unless round trip is stated.)

- Determine voltage drop in grid-tied PV source circuit  
(12AWG stranded, 200FT RT, ISC = 5.2A IMP = 4.95, Temp = 40C)

$$1.98 \text{ Ohm/kFT} * 200/1000 * 4.95\text{A} = 1.96\text{V}$$

- Determine voltage drop in battery charging circuit  
(2AWG, 50FT RT, ISC = 41.6A IMP = 39.6A, Temp = 120C)

$$0.194 \text{ Ohm/kFT} * 50/1000 * 41.6\text{A} * (1 + 0.00323 * (120\text{C} - 75\text{C})) = 0.46\text{V}$$

- Is this acceptable for a 12V system with 2%-3% voltage drop?

$$0.46\text{V} / 12\text{V} = .03833 * 100 = 3.8\%, \text{ NO}$$
